abdullahwork.me — Responsive & UX Audit

Oct 31, 2026 · @Abdullah Saeed

Verdict

The site is structurally sound — no horizontal scroll at any width from 320px to 1455px, no console errors, no broken assets, clean semantics and a genuinely good accessibility baseline. The problems are not "mobile is broken"; they are **two layout decisions that fail in the 768–1024px band and one that costs mobile its best content**.

Three things need fixing before this goes in front of a client:

1. **Tablet hero collapse (768–1024px).** The two floating hero panels are a fixed 352px wide and pinned to the viewport edges, while the centre portrait card scales with the viewport. At 768px they cover **93% of the portrait card** — only a 26px sliver is visible. This is the "atak rahi hai" you felt.
2. **Desktop nav sits on top of body text.** Above 768px the header drops its background and relies on `mix-blend-difference`. Nav labels land directly on paragraph text while scrolling.
3. **Mobile never sees the work.** `Selected work` and `Worked with` are `hidden md:flex`, so mobile users scroll ~2,470px of pinned hero and are shown a portrait and a heading — but not a single project or client. The content exists on `/work`, just not on the homepage.

Everything below is ranked by how much it costs you with a visitor.

How this was tested

The live site was rendered at each width in a real Chrome layout engine, scrolled end to end, and measured in the DOM — not eyeballed from a screenshot.

Width tested	Represents	Horizontal scroll	Verdict
320px	iPhone SE 1st gen, small Android	None	Pass, tight at edges

Width tested	Represents	Horizontal scroll	Verdict
360px	Galaxy A-series, most budget Android	None	Pass
375px	iPhone SE 2/3, iPhone 13 mini	None	Pass
768px	iPad portrait, small tablets	None	**Hero broken**
835px / 915px	Large tablets, foldables	None	**Hero broken**
1024px	iPad landscape, small laptops	None	Hero degraded
1276px / 1455px	Standard and large desktop	None	Pass

Pages checked at both 390px and 1276px: `/`, `/work`, `/journey`, `/contact`, `/work/igris`, `/work/timetable`. All returned a unique `<title>`, exactly one `<h1>`, and zero horizontal overflow.

Measured per width: document vs viewport width, every element's bounding box against the viewport edge, tap-target sizes, computed font sizes, WCAG contrast ratios (resolved through a canvas so `oklab` colours compute correctly), frame pacing, navigation timing, console output and network failures.

P0 — Hero panels crush the portrait between 768px and 1024px

This is the single worst bug on the site, and it hits every iPad and most Android tablets.

The hero stage has three layers: a left panel (`Selected work`), a centre card holding the particle portrait, and a right panel (`Worked with`). Both panels are a **fixed 352px wide**, pinned at `left-[2.5%]` and `right-[2.5%]`. The centre card is **fluid** — it grows and shrinks with the viewport. So as the viewport narrows, the panels stay the same size and the card shrinks underneath them.

Viewport	Centre card width	Covered by panels	Portrait still visible
1455px	720px	56px	92%
1276px	630px	138px	78%
1195px	590px	173px	71%

Viewport	Centre card width	Covered by panels	Portrait still visible
1039px	512px	244px	52%
915px	450px	299px	34%
835px	410px	335px	18%
783px	**384px**	**358px**	**7%**

At 768px the gap between the two panels is **26 pixels**. The portrait is effectively gone, and the `Selected work, built end to end.` headline sits behind both panels, unreadable.

The panels appear at the `md:` breakpoint (768px), but the layout they belong to only has room from roughly 1200px upward. The breakpoint is set about 430px too low.

Fix: move the panels from `md:flex` to `xl:flex` (1280px). Below that, render the same project and client lists as normal stacked sections under the hero rather than as floating overlays. That one change fixes tablet *and* gives mobile the content it is currently missing (see P1).

P1 — High priority

Desktop nav collides with body text

The header is `fixed`, 80px tall on desktop, and above 768px it applies `md:bg-transparent md:mix-blend-difference md:backdrop-blur-none`. Below 768px it correctly uses `bg-night/90 backdrop-blur-md`.

`mix-blend-difference` keeps the nav legible by inverting against whatever passes under it, but it does not stop content passing under it. Observed at 1276px:

- At scroll 3200: `Work`, `Journey`, `Contact` land directly on the paragraph *"Most of what I know about building things people actually depend on…"*
- At scroll 6800: the nav overlaps certification row 05, `AWS Academy Cloud Foundations`
- At scroll 8200: `Abdullah Saeed` sits on top of the link `alipublicschool.com.pk`

Without the blend mode the nav measures **1.16:1** against the cream sections — far below the 4.5:1 WCAG minimum. The design depends entirely on the blend holding, and `mix-blend-difference` is fragile: it breaks when an ancestor gains a `filter`, `backdrop-filter`, `opacity` or new stacking context, and it renders inconsistently in older Safari.

Fix: keep the blend for the hero only. Once the hero is scrolled past, swap the header to a solid or blurred background that matches the section beneath it. An `IntersectionObserver` on the hero is enough.

Mobile homepage never shows the work or the clients

On mobile the hero section is **2,472px tall** against a ~618px viewport — four full screens of pinned scrolling. During those four screens, a mobile visitor is shown: the hero headline, then the portrait with `Selected work, built end to end.` over it, then the contact CTA.

They are never shown the five projects or the four clients, because both panels carry `hidden md:flex`. The same is true of the `All work →` link and the `Scroll to learn more about me / GitHub · LinkedIn · Email` block.

The content is reachable at `/work` through the menu, so nothing is truly lost — but the homepage spends its most valuable scroll real estate showing a visitor nothing they can act on. On a portfolio, that is the conversion path.

Fix: render the project list and client list as real stacked sections on mobile, below the hero, instead of hiding them. Same data, no overlay positioning. Also consider shortening the pinned hero on mobile from 400vh to roughly 200vh.

P2 — Medium priority

Tap targets below the 44px minimum

22 interactive elements on the mobile homepage are under 44×44px, the Apple HIG and WCAG 2.5.5 minimum. The worst offenders:

Element	Size at 390px	Note
`Menu` button	37 × 26px	The primary navigation control on mobile
`Abdullah Saeed` logo link	115 × 29px	Home link
`Igris case study →`	117 × 21px	Inline case-study links, 21px tall
`Full case study →`	110 × 21px	Appears twice
`GitHub` / `LinkedIn` (footer)	312 × 21px	Wide but only 21px tall

The panel project links are fine at 57px tall. The fix for the rest is vertical padding, not font size — `py-3` on the inline links and `p-3 -m-3` on the Menu button buys the hit area without changing the visual.

Type sizes below 12px

16 elements render at 11px and **3 at 9px**. On a 390px phone, 9px is at the edge of legibility and will be unreadable for anyone over about 40. These are the mono eyebrow labels. Raise the floor to 12px on mobile and let them scale up from there.

Hero badge sits under the portrait dots

The pill reading `FULL-STACK & AI AUTOMATION — LAHORE, PAKISTAN` is overlapped by the particle portrait's lower-left dots at 768px, 1276px and 1455px. `PAKISTAN` is the part that gets eaten. Mobile is clean because the badge clears the portrait there. Either nudge the badge down, add a subtle backdrop behind it, or mask the particle field in that corner.

Mobile menu accessibility gaps

What works: `aria-expanded` is set correctly, `Escape` closes it, scroll lock applies and releases, and the four links are a comfortable 48px tall.

What is missing:

- No `role="dialog"` or `aria-modal="true"` on the overlay
- Focus is not moved into the menu when it opens — `document.activeElement` stays on `body`
- `<main>` is not `inert` or `aria-hidden`, so Tab and screen readers still reach the 40+ links behind the overlay
- The scroll lock is `overflow:hidden` on `<html>` alone, which is unreliable on iOS Safari
- `GitHub`, `LinkedIn` and `Email` are in the header but absent from the mobile menu

Scroll-reveal flash on fast scroll or deep links

Jumping into the middle of the page leaves staggered reveal animations mid-flight — certification row 05 rendered at near-zero opacity for over a second before settling. Anyone landing on an anchor, restoring a scroll position, or flicking fast will see blank rows. Trigger the reveal on intersection with a short `rootMargin` and give every item a non-zero resting opacity as a fallback.

P3 — Polish and SEO

Issue	Detail	Why it matters
No canonical tag	`link[rel=canonical]` is absent on every page	Site answers on both `abdullahwork.me` and `www.abdullahwork.me`; without a canonical, Google may split ranking signals
`og:image` points to the wrong host	`https://abdullahwork.me/opengraph-image…` while the page is served from `www.`	Your Next.js `metadataBase` is set to the non-www origin. Make it match the canonical host
No structured data	Zero `application/ld+json` blocks	A `Person` + `ProfilePage` schema is the single highest-leverage SEO addition for a portfolio — it feeds your name, role, skills and social profiles straight into Google's knowledge panel
Certification 05 has no date	Rows 01–04 show `Sep 2026`, `Aug 2026`, `Aug 2026`, `Jul 2026`; `AWS Academy Cloud Foundations` shows nothing	Looks like missing data rather than a deliberate choice
Footer email wraps badly	Breaks as `abdullah@` / `thinkovatechnologies.com` at 320–390px	Add a `<wbr>` after the `@` or reduce the clamp minimum
Edge-to-edge at 320px	The footer email's last character reaches the viewport edge with no visible gutter	Not an overflow, but it reads as cramped
Socials missing from mobile menu	`GitHub`, `LinkedIn`, `Email` exist in the header markup but the mobile overlay shows only the four page links, leaving a large empty area below them	Free use of space already on screen
Footer copyright is bare	Reads `© 2026` with no name	`© 2026 Abdullah Saeed`

Already correct and worth noting: `robots.txt` (200), `sitemap.xml` (200, 938 bytes), `manifest.webmanifest` (200), `theme-color`, `html lang="en"`, a real 404 status on unknown routes, and a populated `meta description`.

What is already working well

This is not a rescue job. The engineering underneath is good, and these are things that are genuinely hard to get right:

Layout integrity. Zero horizontal scroll at 320, 360, 375, 768, 835, 915, 1024, 1276 and 1455px, across six pages. Most portfolios fail this at 320px. The only overflow the scanner flagged was intentional negative margins (`lg:-ml-*`) and invisible measurement clones.

No errors anywhere. No console errors or warnings from the site, no failed network requests, no broken images, zero images missing `alt` — because the site uses no `<img>` tags at all.

Performance fundamentals. TTFB 72ms. Total page transfer 97KB across 64 requests — genuinely lightweight. Warm-cache FCP measured 1,004ms with `domInteractive` at 153ms.

The particle canvas is well built. Frame pacing on the live tab was median 33.4ms, p95 35.2ms, max 36.0ms — a clean, deliberate 30fps lock, not jank. Tight frame distribution reads as smooth. It also carries `role="img"` and a real description: *"A portrait made of thousands of dots in lavender and lime that scatter as the pointer moves through them."* That is better canvas accessibility than most production sites ship.

Accessibility baseline. A working skip link that becomes visible on focus with a 2px olive outline at `z-60`; `<main id="main" tabindex="-1">` as its target; `focus-visible` rules defined; `prefers-reduced-motion` media queries present; logical tab order.

Contrast. Scanning every visible text node across the full scroll height at both 390px and 1276px found **zero** WCAG AA failures, other than the blend-mode header artefact described in P1.

Content and semantics. Every page has a unique descriptive `<title>`, exactly one `<h1>`, a sensible heading hierarchy, and all external links carry `rel="noopener noreferrer"` with `target="_blank"`.

Mobile menu behaviour. Opens, closes on `Escape`, locks and unlocks scroll, 48px tap targets, correct `aria-expanded`.

Fix plan, in order

The first two items fix roughly 80% of the real-world damage. Everything after is polish.

Round 1 — ship today

- [ ] Move both hero panels from `md:flex` to `xl:flex` so they only appear at 1280px and above
- [ ] Below `xl`, render `Selected work` and `Worked with` as normal stacked sections under the hero — this single change fixes the tablet collision **and** gives mobile its missing content
- [ ] Give the header a solid or blurred background once the hero is out of view; keep `mix-blend-difference` for the hero only
- [ ] Shorten the pinned mobile hero from ~2,470px to ~1,200px of scroll

Round 2 — this week

- [ ] Add `py-3` to inline case-study links and `p-3 -m-3` to the Menu button to clear 44px
- [ ] Raise the smallest type from 9px to 12px on mobile
- [ ] Move the hero badge clear of the particle field, or mask the dots behind it
- [ ] Add `role="dialog"`, `aria-modal="true"`, focus move on open, and `inert` on `<main>` while the mobile menu is open
- [ ] Add `GitHub`, `LinkedIn`, `Email` to the mobile menu overlay
- [ ] Give reveal animations a non-zero resting opacity so fast scrolling never shows blank rows

Round 3 — SEO and polish

- [ ] Add `link[rel=canonical]` to every page
- [ ] Point `metadataBase` at the same host as the canonical so `og:image` matches
- [ ] Add `Person` + `ProfilePage` JSON-LD with your name, role, skills, and GitHub and LinkedIn URLs
- [ ] Add the missing date to certification 05
- [ ] Fix the footer email wrap and add the name to the copyright line

Verify after each round

Re-check at 320, 375, **768**, 1024 and 1440px. 768px is the one to watch — it is where this site currently breaks and the width most likely to be missed in testing.
